Part of this lecture has been given at the Dresden University of Technology in Germany

# Graph Coloring

- \* Given an undirected graph  $G=(V,E)$ , the graph coloring problem (GCP) consists of assigning a color  $c_i (1 \leq c_i \leq k)$  to each vertex such that adjacent vertices receive different colors and the number of colors used  $k$  is minimized.

# Optimization or Decision?

- \* GCP—**Optimization** Problem (NP Hard):
  - \* To find the **smallest** number of colors  $k$ .
- \*  $k$ -Coloring—**Decision** Problem (NP Complete):
  - \* Given a  $k$ , we are asked whether there exists a coloring such that all the adjacent coloring constraints are satisfied.
- \* The **Optimization** version of GCP can be solved by tackling a series of the **Decision** version of GCP problem with a gradually decreasing  $k$ .
- \* Thus, these two versions are equivalent to each other.

# Solution Procedure

- \* We start from an initial  $k$  and solve the  $k$ -coloring problem. As soon as the  $k$ -coloring problem is solved, we decrease  $k$  by setting  $k$  to  $k-1$  and solve again the  $k$ -coloring problem.
- \* This process is repeated until no legal  $k$ -coloring can be found.
- \* Smaller  $k \rightarrow$  harder  $k$ -coloring problem. Thus, the solution approach just described solves thus a series of  $k$ -coloring problems of increasing difficulty.
- \* We only consider the  $K$ -coloring problem in this presentation.

# ILP Formulation

$$x_{v,c} = \begin{cases} 1 & \text{if vertex } v \text{ is coloured with colour } c \\ 0 & \text{otherwise} \end{cases}$$

$$\sum_{c=1}^k x_{v,c} = 1 \quad \forall \text{ vertices } v \in V$$

$$x_{u,c} + x_{v,c} \leq 1 \quad \forall \text{ colours } c \in K \quad \forall \text{ edges } \{u, v\} \in E$$

- \* Given  $k$  colors,  $x_{v,c}$  is the decision variables.
- \* The first constraint requires that each vertex receives only one color.
- \* The second constraint denotes that adjacent vertices should receive different colors.

# Assignment Representation

- \* A solution of k-coloring problem can be represented as a series of colors that each vertex receives:
- \*  $S = \{c_1, c_2, \dots, c_n\}$  where  $c_v$  denotes the color of vertex  $v$ . It is required that for any  $(u, v) \in E$ ,  $c_u \neq c_v$ .
- \* This representation is **natural**, but not **intuitive** and **essential**.

# Grouping Representation

- \* The feasible solution of  $k$ -coloring problem can also be presented as a set of independent sets, where an independent set is a set of non-adjacent vertices.
- \*  $S = I_1 \cup I_2 \cup \dots \cup I_k$ , where
  1.  $I_j \cap I_l = \emptyset$  for any  $j$  and  $l$
  2.  $I_1 \cup I_2 \cup \dots \cup I_k = V$
  3.  $I_j$  is an independent set for any  $j$ .
- \* Thus, the  $k$ -coloring problem becomes to partition the  $N$  vertices into  $k$  independent sets.

# Applications

- \* Mobile radio frequency assignment
- \* Timetabling: Education, transportation, sports
- \* Register allocation
- \* Crew scheduling
- \* Printed circuit testing
- \* Air traffic flow management
- \* Satellite range scheduling
- \* Routing and wavelength assignment in WDM networks

# Literature Review (1)

## Constructive Greedy Algorithms

- \*The first heuristic approaches to solving the graph coloring problem, which color the vertices of the graph one by one guided by a greedy function.
- \*They are very fast by nature but their quality is unsatisfactory.
- \*The best known algorithms in this class are:
  - \* the *largest saturation* degree heuristic (DSATUR) (D. Brelaz, 1979)
  - \* *recursive largest first* heuristic (RLF) (F.T. Leighton, 1979)
- \*Often used to generate initial solutions for advanced algorithms

# Literature Review (2)

## Local Search Algorithms

- \* One representative example is the so-called *Tabucol* algorithm which is the first application of Tabu Search to graph coloring ([Hertz, de Werra, 1987](#))
- \* Other local search metaheuristic methods include:
  - \* Simulated Annealing ([Johnson et al, 1991](#))
  - \* Iterated Local Search ([Chiarandini and Stutzle, 2002](#))
  - \* Reactive Partial Tabu Search ([Blochliger, Zufferey, 2008](#))
  - \* GRASP ([Laguna, Marti, 2001](#))
  - \* Variable Neighborhood Search ([Avanthay et al, 2003](#))
  - \* Variable Space Search ([Hertz et al, 2008](#))
  - \* Clustering-Guided Tabu Search ([Porumbel, Hao, 2009](#))
- \* Interested readers are referred to [[Galinier, Hertz, 2006](#)] for a comprehensive survey of the local search approaches.
- \* I will describe the famous *Tabucol* algorithm in detail.

# Literature Review (3)

## Hybrid Evolutionary Algorithms

\*One of the most recent and very promising approaches is based upon hybridization that embeds a **local search** algorithm into the framework of an **evolutionary algorithm** in order to achieve a better tradeoff between intensification and diversification, see for examples:

- \* Dorne, Hao, 1998
- \* Galinier, Hao, 1999
- \* Galinier, Hertz, Zufferey, 2008
- \* Malaguti, Monaci, Toth, 2008
- \* Porumbel, Hao, Kuntz, 2009

# Initial Solution——DSATUR

- \*The heuristic of DSATUR(Degree of Saturation) is to sequentially color vertices according to a DANGER-based heuristic. The main idea of DSATUR is based on least saturation degree.
- \*At each phase, it consists of two steps: The first is to choose a vertex to color and the other is to choose a color for the chosen vertex.

# Initial Solution——DSATUR

- \* DSATUR starts by assigning color 1 to a vertex of maximal degree.
- \* Suppose  $F$  is a partial coloring of the vertices of  $G$ . The degree of saturation of a vertex  $x$ ,  $\text{deg}_s(x)$ , is the number of available colors that vertex  $x$  can use.
- \* The vertex to be colored next in the sequential coloring procedure of DSATUR is a vertex  $x$  with smallest  $\text{deg}_s(x)$ , breaking ties by favoring vertex with larger uncolored degree.
- \* When deciding a color for a chosen vertex the color that is least likely to be required by neighboring vertices is selected.

# DSATUR

## 1. Initialization:

- \*Color[N] = -1
- \*Vetex\_Color\_Avail[N][K]=1
- \*Num\_Avail\_Colors[N]=K
- \*Vertex\_Uncolored\_Degree[N]=Degree[K]

## 2. Choose the vertex v1 with the largest degree, color v1 with color 1

Color[v1] = 1 ;

for v1's adjacent vertices vj

Vetex\_Color\_Avail[vj][1] = 0 ;

Num\_Avail\_Colors[vj] -- ;

Vertex\_Uncolored\_Degree[vj] -- ;

# DSATUR

3. for( $i = 2 ; i \leq N ; i ++$ )
  - \* 3.1 choose a vertex  $v_i$  according to:
    - \*  $\langle \text{Num\_Avail\_Colors}[v_i] (\text{small}), \text{Vertex\_Uncolored\_Degree}[v_i](\text{large}) \rangle$
  - \* 3.2 choose a color  $k_i$  for vertex  $v_i$ :
    - \* for each available color  $j$  for vertex  $v_i$
    - \* calculate the number of uncolored vertices for which color  $j$  is available
    - \* choose color  $k_i$  with the smallest value of this number
  - \* 3.3 color vertex  $v_i$  with color  $k_i$  and updating:
    - \*  $\text{Color}[v_i] = k_i ;$   
for  $v_i$ 's adjacent vertices  $v_j$ 
      - $\text{Vertex\_Uncolored\_Degree}[v_j] -- ;$
      - if( $\text{Vertex\_Color\_Avail}[v_j][k_i] == 1$ )
        - $\text{Num\_Avail\_Colors}[v_j] -- ;$
        - $\text{Vertex\_Color\_Avail}[v_j][k_i] = 0 ;$

# Improvements for DSATUR

- \* It is possible to improve DSATUR heuristic by considering more sophisticated information.
- \* For example, in case of choosing a color for the vertex, it would be better to consider the number of available colors.
- \* What else heuristics can be inspired in choosing vertex and choosing color?

# Local Search

*TabuCol*

# Search Space

- \* In this paper, we adapt the ***k-fixed penalty strategy*** which is also used by many coloring algorithms.
- \* For a given graph  $G = (V; E)$ , the number  $k$  of colors is fixed and the search space contains all possible (legal and illegal)  $k$ -colorings.
- \* A  $k$ -coloring is represented by  $S = \{V_1, \dots, V_k\}$  such that  $V_i$  is the set of vertices receiving color  $i$ .
- \* Thus, if for all  $V_i$  are independent sets, then  $S$  is a legal  $k$ -coloring. Otherwise,  $S$  is an illegal (or conflicting)  $k$ -coloring.

# Evaluation Function

- \* The optimization objective is then to minimize the number of conflicting edges (referred to *conflict number* hereafter) and find a legal  $k$ -coloring in the search space.
- \* Given a  $k$ -coloring  $S = \{V_1, \dots, V_k\}$ , the evaluation function  $f$  counts the conflict number induced by  $S$  such that

$$f(S) = \sum_{\{u,v\} \in E} \delta_{uv}$$

where

$$\delta_{uv} = \begin{cases} 1, & \text{if } u \in V_i, v \in V_j \text{ and } i = j, \\ 0, & \text{otherwise.} \end{cases}$$

# Initial Coloring

- \* The initial solution of our algorithm is randomly generated, i.e., each vertex in the graph is randomly assigned a color from 1 to  $k$ .
- \* Other greedy constructive heuristics are possible, like DSATUR, RLF, DANGER, etc.
- \* However, we observe that strong local search algorithms are not sensitive to the initial solutions.

# Neighborhood Moves

- \* A neighborhood of a given  $k$ -coloring is obtained by moving a **conflicting** vertex  $u$  from its original color class  $V_i$  to another color class  $V_j$  (denoted by  $\langle u, i, j \rangle$ ), called “**critical** one-move” neighborhood.
- \* Therefore, for a  $k$ -coloring  $S$  with cost  $f(S)$ , the size of this neighborhood is bounded by  $O(f(S) \times k)$ .

# An Example

\*  $f = 4$

\* Conflicting pairs: (1,3), (1,4), (7,8), (5,6)

\* Critical One-Move: Only considers vertices 1, 3, 4, 7, 8, 5, 6. Totally  $7*2=14$  moves.

# Neighborhood Evaluation

- \* In order to evaluate the neighborhood efficiently, we employ an **incremental evaluation** technique.
- \* The effect of each move on the objective function can be quickly calculated by a special data structure.
- \* Each time a move is carried out, only the move values affected by this move are updated accordingly.

# Adjacent-Color Table

| Vertex | Red<br>V <sub>1</sub> | Green<br>V <sub>2</sub> | Blue<br>V <sub>3</sub> |
|--------|-----------------------|-------------------------|------------------------|
| 1      | <u>2</u>              | 1                       | 0                      |
| 2      | 1                     | <u>0</u>                | 1                      |
| 3      | <u>1</u>              | 1                       | 0                      |
| 4      | <u>1</u>              | 2                       | 0                      |
| 5      | 0                     | 2                       | <u>1</u>               |
| 6      | 0                     | 0                       | <u>1</u>               |
| 7      | 1                     | <u>1</u>                | 1                      |
| 8      | 2                     | <u>1</u>                | 1                      |
| 9      | 0                     | 2                       | <u>0</u>               |

- \* This matrix  $M[u][i]$  ( $N \times k$ ) measures the number of adjacent vertices if vertex  $u$  receives color  $i$ .
- \* Thus, the incremental move value of a move  $\langle u, i, j \rangle$  can be quickly calculated as:  

$$\Delta(u, i, j) = M[u][j] - M[u][i]$$

# Updating of Adjacent-Color Table

| Vertex | Red<br>V1           | Green<br>V2         | Blue<br>V3 |
|--------|---------------------|---------------------|------------|
| 1      | 2                   | <u>1</u>            | 0          |
| 2      | $1-1=0$             | $\underline{0+1=1}$ | 1          |
| 3      | $\underline{1-1=0}$ | $1+1=2$             | 0          |
| 4      | $\underline{1-1=0}$ | $2+1=3$             | 0          |
| 5      | 0                   | 2                   | <u>1</u>   |
| 6      | 0                   | 0                   | <u>1</u>   |
| 7      | 1                   | <u>1</u>            | 1          |
| 8      | 2                   | <u>1</u>            | 1          |
| 9      | 0                   | 2                   | <u>0</u>   |

- \* Move (1, v1, v2):
- \* Only its adjacent vertices 2, 3 and 4 are affected, and only the v1 and v2 columns need to be updated.
- \* All old color (v1) columns decrease by 1.
- \* All new color (v2) columns increase by 1.

# Simple Local Search

1. Generate initial solution  $S$ , Calculate  $f(S)$
2. Initialize the adjacent-color table  $M$ .
3. While {there exist improving moves}
  - 3.1 Construct the neighborhood of  $S$ , denoted by  $N(S)$
  - 3.2 Calculate the  $\Delta$  values of all critical one-moves
  - 3.3 Find the best move with the least  $\Delta$  value
  - 3.4 Perform the best move:  $f' = f + \Delta_{best}$
  - 3.5 Update the adjacent-color table  $M$
- End

# Tabu Search

## Escaping from Local Optimum

- \* Tabu Search incorporates a tabu list as a “recency-based” memory structure to assure that solutions visited within a certain span of iterations, called tabu tenure, will not be revisited.
- \* TS then restricts consideration to moves not forbidden by the tabu list, and selects a move that produces the best move value to perform.

# Tabu Search

- \* 1. What?
- \* 2. Tenure?
- \* 3. How to judge if a move is forbidden?

# Attributes or Solution?

- \* It should be noted that we generally forbid **attributes** of solutions, but not the **solutions** themselves, since it is too expensive to forbid **solutions**.
- \* For the tabu list, once move  $\langle u, i, j \rangle$  is performed, vertex  $u$  is forbidden to move back to color class  $V_i$  for the next  $tt$  iterations.

# Tabu Tenure

- \* For the tabu list, once move  $\langle u, i, j \rangle$  is performed, vertex  $u$  is forbidden to move back to color class  $V_i$  for the next  $tt$  iterations.
- \* Here, the tabu tenure  $tt$  is dynamically determined by
$$tt = f(S) + r(10)$$
where  $r(10)$  takes a random number in  $\{1, \dots, 10\}$ .

# TabuTenure Table

| Vertex | Red<br>V1 | Green<br>V2 | Blue<br>V3 |
|--------|-----------|-------------|------------|
| 1      | 9         | 0           | 0          |
| 2      | 0         | 10          | 0          |
| 3      | 0         | 0           | 0          |
| 4      | 0         | 0           | 0          |
| 5      | 0         | 0           | 0          |
| 6      | 0         | 0           | 0          |
| 7      | 0         | 0           | 0          |
| 8      | 0         | 0           | 0          |
| 9      | 0         | 0           | 0          |

- \* At the beginning of the search, the TabuTenure table is initialized to be zero.
- \* once move  $\langle u, i, j \rangle$  is performed, the value of  $\text{Table}[u][i] = \text{TabuTenure}$ .
- \* Once the search progresses, the non-zero value of the table is decreased by one at each time.
- \* In the following search, we can decide if a move  $\langle u, i, j \rangle$  is tabu by checking if  $\text{Table}[u][j] > 0$ .

# Fast Implementation of TabuTenure Table

| Vertex | Red<br>V1 | Green<br>V2 | Blue<br>V3 |
|--------|-----------|-------------|------------|
| 1      | 1+10      | 0           | 0          |
| 2      | 0         | 2+15        | 0          |
| 3      | 0         | 0           | 0          |
| 4      | 0         | 0           | 3+12       |
| 5      | 0         | 0           | 0          |
| 6      | 0         | 0           | 0          |
| 7      | 0         | 4+10        | 0          |
| 8      | 0         | 0           | 0          |
| 9      | 0         | 0           | 5+12       |

- \* The above Table[u][i] records the **relative** tabu tenure length. Why not record the **absolute** tabu tenure length?
- \* Once move  $\langle u, i, j \rangle$  is performed, the value of Table[u][i] = TabuTenure+Iter.
- \* In the following search, we can decide if a move  $\langle u, i, j \rangle$  is tabu by checking if Table[u][i] > Iter.
- \* In this way, the tabu **tenure** table can be updated in O(1).

# Aspiration

- \* If one move can **override** the best found solution found so far, it is accepted even if it is in tabu status.
- \* This is because only the **attributes** but not **solutions** themselves are stored in the tabu table.

# TS Algorithm

1. Generate initial solution  $S$ , Calculate  $f(S)$
2. Initialize the adjacent-color table  $M$ .
3. While {stop condition is not met}
  - 3.1 Construct the neighborhood of  $S$ , denoted by  $N(S)$
  - 3.2 Calculate the  $\Delta$  values of all critical one-moves
  - 3.3 Find the best tabu and non-tabu moves with the least  $\Delta$  value
  - 3.4 If {the aspiration condition is satisfied}  
perform the best tabu move,  
else  
perform the best non-tabu move
  - 3.5 Update  $f$  and the adjacent-color table  $M$
- End

# TS Algorithm

- \* Data Structures: Sol[N], f, BestSol[N], Best\_f, TabuTenure[N][K], Adjacent\_Color\_Table[N][K]
- \* Subfunctions:
  - \* Initialization(): Initialize the values of the data structures.
  - \* FindMove(u,vi,vj,delt): find the best non-tabu or tabu move.
  - \* MakeMove(u,vi,vj,delt): update the corresponding values.
- \* TabuSearch()
  - \* { int u, vi, vj, iter = 0;
  - \* Initialization();
  - \* while( iter < MaxIter) {
  - \*     FindMove(u,vi,vj,delt);
  - \*     MakeMove(u,vi,vj,delt); }
  - \* }

# Find Move

```
* FindMove(u,vi,vj,delt)
* {
*   for(i=1:N)
*     if(Adjacent_Color_Table[ i ][ Sol[i] ] > 0) {
*       for( k = 1: K)
*         if( k != Sol[i] ) {
*           calculate delt value of the move <i, Sol[i], k>
*           {
*             if (Table[i][k] < iter)  update the tabu best move;
*             else  update the non-tabu best move;
*           }
*         }
*       if(the tabu best move satisfies the tabu aspiration criterion)
*         <u, vi, vj, delt> = the tabu best move;
*       else  <u, vi, vj,delt> = the non-tabu best move;
*     }
* }
```

# Make Move

```
* MakeMove(u,vi,vj, delt)
* {
*   Sol[ u ] = vj;
*   f = f + delt;
*   Table[ u ][ vi ] = iter + f + rand()%10;
*   Update the Adjacent_Color_Table;
* }
```

# Crossover Operator (2)

- \* A legal  $k$ -coloring is a collection of  $k$  independent sets.
- \* With this point of view, if we could maximize the size of the independent sets by a crossover operator as far as possible, it will in turn help to push those left vertices into independent sets.
- \* In other words, the more vertices are transmitted from parent individuals to the offspring within  $k$  steps, the less vertices are left unassigned.
- \* In this way, the obtained offspring individual has more possibility to become a legal coloring.

# Crossover Operator (3)

## The GPX crossover algorithm

**Data :** configurations  $s_1 = \{V_1^1, \dots, V_k^1\}$  and  $s_2 = \{V_1^2, \dots, V_k^2\}$

**Result :** configuration  $s = \{V_1, \dots, V_k\}$

**begin**

**for**  $l(1 \leq l \leq k)$  **do**

        if  $l$  is odd, then  $A := 1$ , else  $A := 2$

        choose  $i$  such that  $V_i^A$  has a maximum cardinality

$V_l := V_i^A$

        remove the vertices of  $V_l$  from  $s_1$  and  $s_2$

    Assign randomly the vertices of  $V - (V_1 \cup \dots \cup V_k)$

**end**

# HEA Algorithm Scheme
